SPECIFICATION

TITLE OF THE INVENTION

ENCIPHERING METHOD, DECIPHERING METHOD, RECORDING AND
REPRODUCING METHOD, DECIPHERING DEVICE, DECIPHERING
UNIT DEVICE, RECORDING MEDIUM, RECORDING-MEDIUM
5 MANUFACTURING METHOD, AND KEY CONTROL METHOD

BACKGROUND OF THE INVENTION

The present invention relates to an enciphering
method, deciphering method, recording and reproducing
device, deciphering device, deciphering unit device,
10 recording medium, recording-medium manufacturing method,
and key control method which are for preventing
the digitally recorded data from being copied from
a recording medium.

Compact disks and laser disks have been available
15 as recording mediums that record digitized data (e.g.,
documents, sound, images, or programs). Floppy disks
and hard disks have been used as recording mediums
for computer programs and data. In addition to those
recording mediums, a DVD (digital video disk), which is
20 a large-capacity recording medium, has been developed.

Since the aforementioned various digital recording
mediums record the digital data (including the
compressed or encoded data, which can be decoded later)
as it is, the recorded data can be copied easily to
25 another recording medium without impairing the quality
of sound or the quality of image, which enables a large
number of reproductions to be made, contributing to

literary piracy.

In summary, when the data is copied from a digital recording medium, the data can be copied with the sound quality and picture quality of the master remaining unchanged, or without the deterioration of sound quality or picture quality. This has caused the problem of permitting the wrongful conduct of making unauthorized copies of the original and selling them without paying a royalty.

BRIEF SUMMARY OF THE INVENTION

Accordingly, it is an object of the present invention to provide an enciphering method, deciphering method, recording and reproducing device, deciphering device, deciphering unit device, recording medium, recording-medium manufacturing method, and key control method which are for preventing an unauthorized copy of digital recording mediums.

According to one aspect of the present invention, there is provided an enciphering method comprising the steps of: enciphering data with a first key; and enciphering the first key with each of a plurality of predetermined second keys.

According to another aspect of the present invention, there is provided a recording medium having information items recorded thereon, the information items comprising: first information obtained by enciphering data with a first key; and second

information obtained by enciphering the first key with each of a plurality of predetermined second keys.

According to another aspect of the present invention, there is provided a recording medium manufacturing method comprising the steps of: obtaining
5 first information by enciphering data with a first key; obtaining second information obtained by enciphering the first key with each of a plurality of predetermined second keys; and recording the first and second
10 information on the same recording medium.

According to another aspect of the present invention, there is provided a deciphering method comprising the steps of: inputting first information obtained by enciphering data with a first key and
15 second information obtained by enciphering the first key with each of a plurality of predetermined second keys; deciphering the first key using at least one of the second keys to obtain the first key; determining by a specific method whether or not the obtained first key
20 is correct; and deciphering the data using the first key after the determination to obtain the data.

According to another aspect of the present invention, there is provided a deciphering device comprising: input means for inputting first information obtained by enciphering data with a first key and
25 second information obtained by enciphering the first key with each of a plurality of predetermined second

keys; storage means for storing at least one of the second keys; and deciphering means for deciphering the first key from the second information inputted from the input means using at least one of the second keys in the storage means, determining by a specific method whether or not the obtained first key is correct, and deciphering the data from the first information using the first key after the determination to obtain the data.

According to another aspect of the present invention, there is provided a recording and reproducing device comprising: reading means for reading first information and second information from a recording medium on which the first information obtained by enciphering data with a first key and the second information obtained by enciphering the first key with each of a plurality of predetermined second keys have been stored; storage means for storing at least one of the second keys; and deciphering means for deciphering the first key from the second information read by the reading means using at least one of the second keys in the storage means, determining by a specific method whether or not the obtained first key is correct, and deciphering the data from the first information using the first key after the determination to obtain the data.

According to another aspect of the present

invention, there is provided a key control method comprising the steps of: causing a first caretaker to take custody of a plurality of predetermined second keys; causing a second caretaker to take custody of first information obtained by enciphering data with a first key and second information obtained by enciphering the first key with each of the predetermined second keys; and causing a third caretaker to take custody of at least one of the second keys.

According to another aspect of the present invention, there is provided a deciphering device comprising: reading means for reading first information, second information, and third information from a recording medium on which the first information obtained by enciphering data with a first key, the second information obtained by enciphering the first key with each of a plurality of predetermined second keys, and the third information used for key determination have been stored; storage means for storing at least one of the second keys; first deciphering means for deciphering one of the enciphered first keys selected in the order determined from the second information using one second key selected in the order determined from the second keys stored in the storage means, determining on the basis of the deciphering result and the third information whether or not the first key obtained by the deciphering is correct, and

repeating the selection and the determination until the first key determined to be correct has been obtained; and second deciphering means for deciphering the data from the first information using the first key the first deciphering means has determined to be correct.

According to another aspect of the present invention, there is provided a deciphering device comprising: a first unit built in a driving unit of a recording medium or connected to the driving unit of the recording medium without the CPU bus of a computer, including: means for transferring first information obtained by enciphering the data read from the recording medium with a first key, second information obtained by enciphering the first key with each of a plurality of predetermined second keys, and third information used for key determination in such a manner that at least the second information and third information are transferred safely without being externally acquired; and a second unit connected to the first unit via the CPU bus of the computer including: means for receiving the first information, second information, and third information from the first unit via the CPU bus of the computer in such a manner that at least the second information and third information are received safely without being externally acquired; storage means for storing at least one of the second keys; first deciphering means for deciphering one of the enciphered

first keys selected in the order determined from the second information using one second key selected in the order determined from the second keys stored in the storage means, determining on the basis of the
5 deciphering result and the third information whether or not the first key obtained by the deciphering is correct, and repeating the selection and the determination until the first key determined to be correct has been obtained; and second deciphering means
10 for deciphering the data from the first information using the first key the first deciphering means has determined to be correct.

According to another aspect of the present invention, there is provided a deciphering device
15 comprising: reading means for reading first information, second information, third information, and fourth information from a recording medium on which the first information obtained by enciphering a third key with a first key, the second information obtained by
20 enciphering the first key with each of a plurality of predetermined second keys, the third information used for key determination, and the fourth information obtained by enciphering data with the third key have been stored; storage means for storing at least one
25 of the second keys; first deciphering means for deciphering one of the enciphered first keys selected in the order determined from the second information

using one second key selected in the order determined
from the second keys stored in the storage means,
determining on the basis of the deciphering result and
the third information whether or not the first key
5 obtained by the deciphering is correct, and repeating
the selection and the determination until the first
key determined to be correct has been obtained; second
deciphering means for deciphering the third key from
the first information using the first key the first
10 deciphering means has determined to be correct; and
third deciphering means for deciphering the data from
the fourth information using the third key obtained by
the second deciphering means.

According to another aspect of the present
15 invention, there is provided a deciphering method
comprising the steps of: reading first information,
second information, and third information from
a recording medium on which the first information
obtained by enciphering data with a first key, the
20 second information obtained by enciphering the first
key with each of a plurality of predetermined second
keys, and the third information used for key determi-
nation have been stored; deciphering one of the
enciphered first keys selected in the order determined
25 from the second information using one second key
selected in the order determined from the second keys,
determining on the basis of the deciphering result and

the third information whether or not the first key
obtained by the deciphering is correct, and repeating
the selection and the determination until the first
key determined to be correct has been obtained; and
5 deciphering the data from the first information using
the first key determined to be correct.

According to another aspect of the present
invention, there is provided a deciphering method
comprising the steps of: transferring first information
10 obtained by enciphering the data read from a recording
medium with a first key, second information obtained
by enciphering the first key with each of a plurality
of predetermined second keys, and third information
used for key determination from a first unit built in
15 a driving unit of the recording medium or connected to
the driving unit of the recording medium without the
CPU bus of a computer to a second unit via the CPU bus
of the computer in such a manner that at least the
second information and third information are trans-
20 ferred safely without being externally acquired; and
in the second unit, deciphering one of the enciphered
first keys selected in the order determined from the
second information using one second key selected in
the order determined from the second keys stored in
25 the storage means, determining on the basis of the
deciphering result and the third information whether
or not the first key obtained by the deciphering is

correct, repeating the selection and the determination until the first key determined to be correct has been obtained, and deciphering the data using the first key determined to be correct.

5 According to another aspect of the present invention, there is provided a deciphering method comprising the steps of: reading first information, second information, third information, and fourth information from a recording medium on which the first
10 information obtained by enciphering at least a third key with a first key, the second information obtained by enciphering the first key with each of a plurality of predetermined second keys, the third information used for key determination, and the fourth information
15 obtained by enciphering data with the third key have been stored; deciphering one of the enciphered first keys selected in the order determined from the second information using one second key selected in the order determined from the second keys, determining on the
20 basis of the deciphering result and the third information whether or not the first key obtained by the deciphering is correct, and repeating the selection and the determination until the first key determined to be correct has been obtained; deciphering the third
25 key from the first information using the first key determined to be correct; and deciphering the data from the fourth information using the third key obtained.

According to another aspect of the present invention, there is provided a deciphering unit device that receives information via the CPU bus of a computer from a bus transfer unit built in a driving unit of a recording medium or connected to the driving unit of the recording medium without the CPU bus of the computer and deciphers data on the basis of the information, the deciphering unit device comprising:

5 means for receiving first information obtained by enciphering the data read from the recording medium with a first key, second information obtained by enciphering the first key with each of a plurality of predetermined second keys, and third information used for key determination from the bus transfer unit via the CPU bus of the computer in such a manner that at least the second information and third information are received safely without being externally acquired;

10 storage means for storing at least one of the second keys; first deciphering means for deciphering one of the enciphered first keys selected in the order determined from the second information using one second key selected in the order determined from the second keys stored in the storage means, determining on the basis of the deciphering result and the third

15 information whether or not the first key obtained by the deciphering is correct, and repeating the selection and the determination until the first key determined to

20

25

be correct has been obtained; and second deciphering means for deciphering the data from the first information using the first key the first deciphering means has determined to be correct.

5 In each of the above categories, the data may include at least one of key information, documents, sound, images, and programs.

10 With the present invention, only the correct party having at least one of the second keys can get the first key and therefore can get the plain data of the data enciphered using the first key. As a result, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

15 Moreover, with the present invention, even if the data flowing over the signal line connecting the enciphering unit to the deciphering unit is stored, the stored data cannot be reproduced or used, because the data is the enciphered data. In addition, because the
20 information necessary for enciphering the data is created on the basis of, for example, random numbers, and cannot be reproduced later, the stored data cannot be reproduced or used, even if the second key (master
25 key) in the deciphering unit has been broken. As a result, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

Still furthermore, with the present invention, because the enciphering unit and deciphering unit can be designed separately from the essential portion of the reproducing section of the digital recording and reproducing apparatus, even if the cipher is broken, the enciphering unit and deciphering unit have only to be replaced to overcome this problem.

Additional objects and advantages of the present invention will be set forth in the description which follows, and in part will be obvious from the description, or may be learned by practice of the present invention. The objects and advantages of the present invention may be realized and obtained by means of the instrumentalities and combinations particularly pointed out in the appended claims.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate presently preferred embodiments of the present invention and, together with the general description given above and the detailed description of the preferred embodiments given below, serve to explain the principles of the present invention in which:

FIG. 1 is a block diagram of a system according to a first embodiment of the present invention;

FIG. 2 is a flowchart for the operation of the first embodiment;

FIG. 3 illustrates an example of a format in which the enciphered key and the enciphered data are stored on a recording medium;

FIG. 4 is a diagram to help explain a case where
5 the data is stored from the CPU BUS;

FIG. 5 is a block diagram of a system according to a second embodiment of the present invention;

FIGS. 6A and 6B show examples of the internal structure of the key judging section;

FIG. 7 is a flowchart for the operation of the
10 second embodiment;

FIG. 8 is a flowchart for the operation of the second embodiment;

FIG. 9 is a block diagram of a system according to
15 a third embodiment of the present invention;

FIG. 10 is a flowchart for the operation of the third embodiment;

FIG. 11 is a diagram to help explain the key control method; and

FIG. 12 is a diagram to help explain the
20 enciphering operation.

DETAILED DESCRIPTION OF THE INVENTION

Hereinafter, referring to the accompanying drawings, embodiments of the present invention will be
25 explained.

In the embodiments, the operation of enciphering a certain data item a using key K is expressed as $E_K(a)$

and the operation of deciphering a certain data item
a using key K is expressed as $D_K(a)$. By this way
of expression, the operation of enciphering and
deciphering a certain data item a using key K is
5 expressed as $D_K(E_K(a))$, for example.

In the embodiments, there is a case where
a certain data item is first deciphered and then the
deciphered data item is enciphered to restore the
original data item. This is based on the fact that the
10 deciphering of the data has the same function as the
enciphering of the data. Specifically, to return the
enciphered data to the original data, the key used
for deciphering must be known. Once the key is known,
enciphering the deciphered data produces the original
15 data that was first deciphered. If the cipher key is x
and the data item is y, the operation will be expressed
as:

$$E_X(D_X(Y)) = Y$$

In the embodiments, explanation will be given
20 using an example of a system that reads the image data
compressed and enciphered according to the MPEG 2 data
compression standard from a DVD and enciphers, decodes,
and reproduce the read-out data.

(First Embodiment)

25 Hereinafter, a first embodiment of the present
invention will be explained.

FIG. 1 is a block diagram of a system according to

a first embodiment of the present invention. FIG. 2 is a flowchart for the operation of the first embodiment.

The system related to the first embodiment is connected to the CPU BUS of the CPU (not shown) used for reproduction in a computer, such as a personal computer. The system is designed to allow the enciphered data ($E_{SK}(\text{Data})$ explained later) to flow over the CPU BUS. FIG. 1 shows only the sections related to the CPU used for reproduction.

As shown in FIG. 1, the system of the first embodiment comprises a DVD driving unit (not shown) that reads the data from a DVD 101, an enciphering unit 107 that is connected to the DVD driving unit without the CPU BUS or is built in the DVD driving unit, and a deciphering unit 114.

The enciphering unit 107 and deciphering unit 114 are connected to the CPU BUS 110. The deciphering unit 114 outputs the data via, for example, an I/O port, not via the CPU BUS. That is, in the embodiment, the input and output of the data is carried out without the CPU BUS, whereas the CPU BUS is used for the data transfer between the enciphering unit 107 and the deciphering unit 114.

The enciphering unit 107 includes a demodulation/error correction circuit 117, a demodulation/error correction circuit 118, and an enciphering circuit 104. Although in FIG. 1, the enciphering unit 107 has two

enciphering circuits 104, it is assumed that it actually has one enciphering circuit. The enciphering unit 107 is assumed to be composed of a single independent IC chip. The demodulation/error correction circuit 117 and demodulation/error correction circuit 118 may be provided in the unit (the DVD driving unit) in the preceding stage, not in the enciphering unit 107.

The deciphering unit 114 includes a deciphering circuit 112 and a session key creation circuit 111 that creates a second session key S_K' . In the embodiment, the deciphering unit 114 is assumed to include an MPEG decoder circuit 115 and a converter circuit 116 that converts the digital enciphered image data into analog data. Although in FIG. 1, the deciphering unit 114 has four deciphering circuits 112, it is assumed that it actually has one deciphering circuit. The deciphering unit 114 is assumed to be composed of a single independent IC chip.

In each of the enciphering unit 107 and deciphering unit 114, a master key, explained later, has been registered. It is assumed that the master key has been recorded in a secret area in each of the enciphering unit chip and the deciphering unit chip so that the user cannot externally take out the master key.

A control section (not shown) is assumed to control the entire system. The control section is realized by, for example, executing a program on the

CPU in the computer. Concrete examples of control by the control section include an instruction to read the data from a DVD, the specification of data transfer destination, and an instruction to output the data from the deciphering unit 114. The control section may be triggered, for example, by the user via a user interface, or by a process in an application program.

In the first embodiment, a first session key is represented by S_K , a second session key S_K' , the master key M_K , and image data (i.e., the data to be enciphered) Data.

In FIG. 1, numeral 102 indicates $E_{MK}(S_K)$ created by enciphering the first session key S_K using the master key M_K , 103 $E_{SK}(\text{Data})$ created by enciphering the image data Data using the first session key S_K , 105 the master key M_K , 106 a second session key S_K' , 108 $D_{MK}(S_K')$ created by deciphering the second session key S_K' using the master key M_K , 109 $E_{SK'}(E_{MK}(S_K))$ created by enciphering the first session key $E_{MK}(S_K)$ enciphered with the master key M_K using the second session key S_K' , and 113 the first session key S_K .

As shown in FIG. 3, it is assumed that on the DVD 101, $E_{MK}(S_K)$ created by enciphering the first session key S_K using the master key M_K is recorded in the key recording area (lead-in area) in the innermost circumference portion and the $E_{SK}(\text{Data})$ created by enciphering the image data Data using the first session

key S_K is recorded in the data recording area (data area).

Hereinafter, the operation of the first embodiment will be explained by reference to the flowchart of FIG. 2.

At step S1, the first session key $E_{MK}(S_K)$ enciphered using the master key M_K is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the first session key, and then is loaded into the enciphering unit 107. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

At step S2, in the deciphering unit 114, the session key creation circuit 111 creates a second session key S_K' using random numbers, such as time data from a clock (not shown). Then, the deciphering circuit 112 decipheres the created second session key S_K' using the master key M_K to create $D_{MK}(S_K')$ and sends it to the enciphering unit 107 via the CPU BUS 110.

As the timing of generating random numbers (e.g., the timing of inputting time information), for example, the timing with which the signal indicating that the DVD 101 has been loaded into the DVD driving unit is asserted may be used.

The session creation circuit 111 may be composed of a random-number generator that is as long as the key.

When a key is created using random numbers all of whose bits may take 0s or 1s, it is necessary to perform a check process to prevent all of the bits from taking 0s or 1s.

5 At step S3, using the master key M_K , the enciphering circuit 104 of the enciphering unit 107 enciphers $D_{MK}(S_K')$ received via the CPU BUS 110.

Namely, from $E_{MK}(D_{MK}(S_K')) = S_K'$

10 a second session key S_K' created at the session key creation circuit 111 of the deciphering unit 114 can be obtained.

15 The second session key S_K' created at the session key creation circuit 111 is designed to prevent its contents from being known even if it is stolen on the CPU BUS 110.

Then, at step S4, using the second session key S_K' , the enciphering unit 107 enciphers the enciphered first session key $E_{MK}(S_K)$ recorded on the DVD 101 to create $E_{SK'}(E_{MK}(S_K))$, and sends this to deciphering unit 114.

20 Then, at step S5, the deciphering circuit 112 of the deciphering unit 114 decipheres $E_{SK'}(E_{MK}(S_K))$ received via the CPU BUS 110 using the second session key S_K' and produces:

$D_{SK'}(E_{SK'}(E_{MK}(S_K))) = E_{MK}(S_K)$

25 Furthermore, $E_{MK}(S_K)$ obtained at the deciphering circuit 112 is deciphered using the master key M_K to produce:

$$D_{MK}(E_{MK}(S_K)) = S_K$$

Thus, this gives the first session key S_K .

After the first session key S_K has been obtained as described above, at step S6, the image data

5 $E_{SK}(\text{Data})$ enciphered using the first session key S_K recorded on the DVD 101 by the DVD driving unit (not shown) is read out and loaded into the enciphering unit 107. At that time, the demodulation/error correction circuit 118 performs demodulation and
10 corrects errors in the data. Then, $E_{SK}(\text{Data})$ is sent to the enciphering unit 107 via the CPU BUS 110.

At step S7, the deciphering circuit 112 of the deciphering unit 114 decipheres $E_{SK}(\text{Data})$ received via the CPU BUS 110 using the first session key S_K and
15 produces:

$$D_{SK}(E_{SK}(\text{Data})) = \text{Data}$$

Then, the enciphered image data is deciphered to produce Data.

Then, step S6 and step S7 are repeated until for
20 example, the process of the data to be deciphered (i.e., $E_{SK}(\text{Data})$) has been completed or the stop of the process has been requested.

When the image data Data thus obtained has been compressed according to, for example, the MPEG2 data
25 compression standard, the image data is decoded at an MPEG decoder circuit 115. After the decoded signal has been converted by a D/A converter circuit 116

into an analog signal, the analog signal is sent to an imaging device (not shown), such as a television, which reproduces the image.

5 Step 1 may be executed before or after step S2 and step S3.

Step S6 and step S7 may be executed by the method of carrying out the steps in units of $E_{SK}(\text{Data})$, the method of reading a specific number of $E_{SK}(\text{Data})$ at step S6, storing the read-out data in a buffer
10 temporarily, and then deciphering $E_{SK}(\text{Data})$ in the buffer at step S7, or the method of carrying out step S6 and step S7 in a pipeline processing manner.

Moreover, the deciphering circuit 112 may transfer the image data $E_{SK}(\text{Data})$ to the MPEG decoder circuit
15 115 in units of one Data item or a specific number of Data items.

As described above, with the first embodiment, when the data is reproduced from a medium on which the digitized data has been enciphered and recorded (when
20 the enciphered data is deciphered), the deciphered data is prevented from flowing over the CPU BUS of the computer and the second session key S_K' used to encipher the first session key necessary for deciphering the enciphered data flowing over the CPU BUS is
25 created on the basis of information that changes each time the data is reproduced, such as time information. Therefore, even when the data flowing over the CPU BUS

110 is stored from signal lines 210 into a digital storage medium 211 as shown in FIG. 4, the data cannot be reproduced or used.

As a result, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

Furthermore, with the embodiment, as seen from FIG. 1, because the circuits used for enciphering and deciphering can be designed separately from the essential portion of the reproducing section of the digital recording and reproducing apparatus, such as a DVD, even if the cipher is broken, the deciphering unit 114 (or the enciphering unit 107 and deciphering unit 114) has only to be replaced to overcome this problem.

While in the first embodiment, the enciphering unit 107 has one enciphering circuit, it may have two enciphering circuits. Moreover, although in the embodiment, the deciphering unit 114 has one deciphering circuit, it may have two, three, or four deciphering circuits. In these cases, it is desirable that the enciphering circuits should be paired with the corresponding deciphering circuits and each pair be used independently or in a shared manner.

When a set of an enciphering circuit and the corresponding deciphering circuit is used independently, an enciphering method different from that in another

enciphering circuit and deciphering circuit may be used in the enciphering circuit and its corresponding deciphering circuit in the independent set.

(Second Embodiment)

5 Hereinafter, a second embodiment of the present invention will be explained.

What will be explained in the second embodiment is an example suitable for a case where a plurality of predetermined master keys are prepared and one or more
10 of them are allocated to deciphering unit makers (or DVD makers and distributors)

FIG. 5 is a block diagram of the system according to the second embodiment of the present invention. An example of the operation of the second embodiment is
15 shown in the flowchart of FIGS. 7 and 8.

The system related to the second embodiment is connected to the CPU BUS of the CPU (not shown) used for reproduction in a computer, such as a personal computer. The system is designed to allow the
20 enciphered data ($E_{SK}(\text{Data})$) to flow over the CPU BUS. FIG. 5 shows only the sections related to the CPU used for reproduction.

As shown in FIG. 5, the system of the second embodiment comprises a DVD driving unit (not shown)
25 that reads the data from a DVD 101, an enciphering unit 107 that is connected to the DVD driving unit without the CPU BUS or is built in the DVD driving unit, and

a deciphering unit 114a.

The enciphering unit 107 and deciphering unit 114a are connected to the CPU BUS 110. The deciphering unit 114a outputs the data via, for example, an I/O port, not via the CPU BUS. That is, in the second embodiment, the input and output of the data is carried out without the CPU BUS, whereas the CPU BUS is used for the data transfer between the enciphering unit 107 and the deciphering unit 114a.

The enciphering unit 107 includes a demodulation/error correction circuit 117, a demodulation/error correction circuit 118, and an enciphering circuit 104. Although in FIG. 5, the enciphering unit 107 has two enciphering circuits 104, it is assumed that it actually has one enciphering circuit. The enciphering unit 107 is assumed to be composed of a single independent IC chip. The demodulation/error correction circuit 117 and demodulation/error correction circuit 118 may be provided in the unit (the DVD driving unit) in the preceding stage, not in the enciphering unit 107.

The deciphering unit 114a includes a deciphering circuit 112 and a session key creation circuit 111 that creates a second session key S_K' , and a key judging circuit 120.

FIGS. 6A and 6B show examples of the structure of the key judging circuit 120. The key judging circuit 120 includes a deciphering circuit 112, a comparison

circuit 121, and a gate circuit 122. In the second embodiment, it is assumed that the deciphering unit 114a incorporates an MPEG decoder circuit 115 and a conversion circuit 116 that converts the deciphered digital image data into analog image data.

Although in FIG. 5 and FIGS. 6A and 6B, the deciphering unit 114a has a total of five deciphering circuits 112, including the two deciphering circuits 112 in the key judging circuit 120, it is assumed that it actually has one deciphering circuit.

The deciphering unit 114a is composed of a single independent IC chip.

In each of the enciphering unit 107 and deciphering unit 114a, master keys, explained later, have been registered. It is assumed that the master keys have been recorded in a secret area in each of the enciphering unit chip and the deciphering unit chip so that the user cannot externally take out the master keys.

A control section (not shown) is assumed to control the entire system. The control section is realized by, for example, executing a program on the CPU in the computer. Concrete examples of control by the control section include an instruction to read the data from a DVD, the specification of data transfer destination, and an instruction to output the data from the deciphering unit 114a. The control section

may be triggered, for example, by the user via a user interface, or by a process in an application program.

In the second embodiment, there are an n number of types of master keys. A first session key is represented by S_K , a second session key S_K' , the n-th master key M_{Kt} (t s in the range of 1 to n), and image data (i.e., the data to be enciphered) Data.

In FIG. 5, numeral 102-1 indicates $E_{MKi}(S_K)$ created by enciphering the first session key S_K using the master key M_{Ki} , 102-2 $E_{SK}(S_K)$ created by enciphering the first session key S_K using the first session key S_K itself, 103 $E_{SK}(\text{Data})$ created by enciphering the image data Data using the first session key S_K , 105 the master key M_{Ki} , 106 a second session key S_K' , 108 $D_{MKj}(S_K')$ created by deciphering the second session key S_K' using the master key M_{Kj} , 109-1 $E_{SK'}(E_{MKi}(S_K))$ created by enciphering the first session key $E_{MKi}(S_K)$ enciphered with the master key M_{Ki} using the second session key S_K' , 109-2 $E_{SK'}(E_{SK}(S_K))$ created by enciphering the first session key $E_{SK}(S_K)$ enciphered with the first session key S_K itself using the second session key S_K' and 113 the first session key S_K .

Several methods can be considered as to how to set the number of types of $E_{MKi}(S_K)$ created by enciphering the first session key S_K recorded on the DVD 101 using the master key M_{Ki} and how to set the number of types of master key M_{Kj} the deciphering unit 114a has in it.

For example, they are as follows.

(Method 1) One master key $E_{MKi}(S_K)$ (i is in the range of 1 to n) is recorded on the DVD 101. The deciphering unit 114a has an n number of master keys M_{Kj} ($j = 1$ to n) in it.

(Method 2) An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114a has one master key M_{Kj} (j is in the range of 1 to n) in it.

(Method 3) This is an expansion of Method 2. An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114a has an m ($2 < m < n$) number of master keys M_{Kj} ($j = 1$ to n) in it. The m number of master keys have been selected from the n number of master keys beforehand.

As a concrete example, $n = 100$ or $n = 400$ and $m = 2, 3, 4$, or 10 . The present invention is not limited to these values.

(Method 4) This is the reverse of Method 3. An m ($2 < m < n$) number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The m number of master keys have been selected from an n number of master keys M_{Kj} ($j = 1$ to n) beforehand. The deciphering unit 114a has an n number of master keys M_{Kj} ($j = 1$ to n) in it.

(Method 5) An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114a has an n number of master key M_{Kj}

($j = 1$ to n) in it.

Method 3 to Method 5 have the same deciphering procedure.

As shown in FIG. 3, it is assumed that on the DVD 101, one (in the case of Method 1) or more (in the case of Method 2 to Method 5) $E_{M_{Ki}}(S_K)$ created by enciphering the first session key S_K using the master key M_{Ki} are recorded in the key recording area (lead-in area) in the innermost circumference portion and $E_{S_K}(\text{Data})$ created by enciphering the image data Data using the first session key S_K is recorded in the data recording area (data area).

It is assumed that an n number of master keys M_{Kj} (in the case of Method 1, Method 4, or Method 5), one master key M_{Kj} (in the case of Method 2), or an m number of master keys M_{Kj} (in the case of Method 3) have been registered in the deciphering unit 114a.

A predetermined master key is assumed to have been registered in the deciphering unit 107.

Hereinafter, Method 1, Method 2, and Method 3 to Method 5 will be explained in that order.

First, the operation of the second embodiment in the case of Method 1 will be explained by reference to the flowcharts of FIGS. 7 and 8.

At step S11, the first session key $E_{S_K}(S_K)$ enciphered using the first session key S_K itself is read from the DVD 101, on which the DVD driving unit

(not shown) has recorded the first session key, and then is loaded into the enciphering unit 107. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

5 At step S12, the first session key $E_{MKi}(S_K)$ (i in the range of 1 to n , where i is unknown here) enciphered using the master key M_{Ki} is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the master key, and then is loaded into the
10 enciphering unit 107. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

 At step S13, the session key creation circuit 111 of the deciphering unit 114 creates a second session
15 key S_K' using random numbers, such as time data from a clock (not shown). Then, the deciphering circuit 112 decipheres the created second session key S_K' using the master key M_{Kj} (j is in the range of 1 to n , where j is predetermined) to create $D_{MKj}(S_K')$ and sends it to the
20 enciphering unit 107 via the CPU BUS 110.

 As the timing of generating random numbers (e.g., the timing of inputting time information), for example, the timing with which the signal indicating that the DVD 101 has been loaded into the DVD driving unit is
25 asserted may be used.

 The session creation circuit 111 may be composed of a random-number generator that is as long as the key,

for example. When a key is created using random numbers all of whose bits may take 0s or 1s, it is necessary to perform a check process to prevent all of the bits from taking 0s or 1s.

5 At step S14, using the master key M_{Kj} (j has a predetermined value in the range of 1 to n), the enciphering circuit 104 of the enciphering unit 107 enciphers $D_{MKj}(S_K')$ received via the CPU BUS 110.

Namely, from $E_{MKj}(D_{MKj}(S_K')) = S_K'$

10 a second session key S_K' created at the session key creation circuit 111 of the deciphering unit 114a can be obtained.

15 The second session key S_K' created at the session key creation circuit 111 is designed to prevent its contents from being known even if it is stolen on the CPU BUS 110.

20 Then, at step S15, using the thus obtained second session key S_K' , the enciphering unit 107 enciphers the enciphered first session key $E_{SK}(S_K)$ recorded on the DVD 101 to create $E_{SK'}(E_{SK}(S_K))$, and sends this to deciphering unit 114a in via CPU BUS 110.

25 Similarly, at step S16, using the thus obtained second session key S_K' , the enciphering unit 107 enciphers the enciphered first session key $E_{MKi}(S_K)$ recorded on the DVD 101 to create $E_{SK'}(E_{MKi}(S_K))$, and sends this to deciphering unit 114a.

Then, at step S17, the deciphering circuit 112 of

the deciphering unit 114a decipheres $E_{SK'}(E_{SK}(S_K))$ received via the CPU BUS 110 using the second session key S_K' and produces:

$$D_{SK'}(E_{SK'}(E_{SK}(S_K))) = E_{SK}(S_K)$$

5 Similarly, at step S18, the deciphering circuit 112 of the deciphering unit 114a decipheres $E_{SK'}(E_{MKi}(S_K))$ received via the CPU BUS 110 using the second session key S_K' and produces:

$$D_{SK'}(E_{SK'}(E_{MKi}(S_K))) = E_{MKi}(S_K)$$

10 Because the master key M_{Ki} used in creating $E_{MKi}(S_K)$ is unknown, the first session key S_K is found using the key judging circuit 120 as follows.

First, the principle of the key judging process will be explained.

15 When $E_{MKi}(S_K)$ is deciphered using all of the master keys M_{Kj} ($j = 1$ to n), this gives:

$$S_{Kij} = D_{MKj}(E_{MKi}(S_K)) \quad (j = 1 \text{ to } n)$$

Of these, one S_{Kij} ($j = 1$ to n) is the first session key S_K .

20 Using the $E_{SK}(S_K)$, it is determined which one of the created S_{Kij} ($j = 1$ to n) is the first session key S_K .

Then, when $E_{SK}(S_K)$ is deciphered using all of the candidates S_{Kij} ($j = 1$ to n) of the first session key, 25 this gives:

$$S_{K''}(i, j) = D_{SKij}(E_{SK}(S_K))$$

Here, when the same master key M_{Kj} as the master

key M_{Ki} used in creating $E_{MKi}(S_K)$ is used in the deciphering unit, or when $i = j$, this gives $S_K''(i, j) = S_{Kij} = S_K$

Therefore, when a check is made to see if $S_K''(i, j) = S_{Kij}$ ($j = 1$ to n) holds for each S_{Kij} ($j = 1$ to n), this gives S_{Kij} that meets $S_K''(i, j) = S_{Kij}$ ($j = 1$ to n) as the first session key S_K . The one corresponding to j giving the S_{Kij} is the master key used in the present session.

The operation is expressed in C language notation as follows:

```
for (i=1; i<n+1; i++) {  
    DS1[i]=DMK[i](EMKi(SK));  
    DS2[i]=DSK[i](ESK(SK));  
    if(DS1[i]==DS2[i])  
    {  
        SK1=DS2[i];  
        break;  
    }  
    else      EXIT_MISMATCH;  
}
```

The second line in the above procedure indicates the operation of deciphering $E_{MKi}(S_K)$ using M_{Ki} and substituting the result into $DS1[i]$.

The third line in the procedure indicates the operation of deciphering $E_S(S_K)$ using S_{Ki} and substituting the result into $DS2[i]$.

The fourth line in the procedure indicates the operation of judging whether or not $DS1[i]$ coincides with $DS2[i]$.

5 The ninth line in the procedure indicates the operation executed when $DS1[i]$ does not coincide with $DS2[i]$.

For example, in FIGS. 6A and 6B, the deciphering circuit 112 in the key judging circuit 120 decipheres $EM_{Ki}(S_K)$ for $j = 1$ using master key M_{Kj} , giving:

10 $S_{Kij} = DM_{Kj}(EM_{Ki}(S_K))$

Then, the deciphering circuit 112 decipheres $ES_K(S_K)$ using S_{Kij} , giving:

$S_{K''} = DS_{Kij}(ES_K(S_K))$

15 Next, the comparison circuit 121 compares $S_{K''}$ with S_{Kij} . If they coincide with each other, the gate circuit 122 will be controlled so as to output the stored S_{Kij} (FIG. 6A) or $S_{K''}$ (FIG. 6B) as the first session key S_K .

20 If they do not coincide, j is incremented by one and the same operation will be carried out until the first session key S_K has been obtained.

After the first session key S_K has been obtained as described above, at step S20, the image data $ES_K(\text{Data})$ enciphered using the first session key S_K recorded on the DVD 101 by the DVD driving unit (not shown) is read out and loaded into the enciphering unit 107. At that time, the demodulation/error

25

correction circuit 118 performs demodulation and corrects errors in the data. Then, $E_{SK}(\text{Data})$ is sent to the enciphering unit 107 via the CPU BUS 110.

At step S21, the deciphering circuit 112 of the
5 deciphering unit 114a decipheres $E_{SK}(\text{Data})$ received via the CPU BUS 110 using the first session key S_K and produces:

$$D_{SK}(E_{SK}(\text{Data})) = \text{Data}$$

Then, the enciphered image data is deciphered to
10 produce Data.

Then, step S20 and step S21 are repeated until for example, the process of the data to be deciphered (i.e., $E_{SK}(\text{Data})$) has been completed or the stop of the process has been requested.

When the image data Data thus obtained has been
15 compressed according to, for example, the MPEG2 data compression standard, the image data is decoded at an MPEG decoder circuit 115. After the decoded signal has been converted by a D/A converter circuit 116
20 into an analog signal, the analog signal is sent to an imaging device (not shown), such as a television, which reproduces the image.

Any one of step S11, step S12, and steps S13 and S4 may be executed first.

Moreover, either step S15 and step S17 or step S16
25 and S18 may be executed first.

Step S20 and step S21 may be executed by the

method of carrying out the steps in units of $E_{SK}(\text{Data})$,
the method of reading a specific number of $E_{SK}(\text{Data})$
at step S20, storing the read-out data in a buffer
temporarily, and then deciphering $E_{SK}(\text{Data})$ in the
5 buffer at step S21, or the method of carrying out step
S20 and step S21 in a pipeline processing manner.

Moreover, the deciphering circuit 112 may transfer
the image data $E_{SK}(\text{Data})$ to the MPEG decoder circuit
115 in units of one Data item or a specific number of
10 Data items.

As described above, with the second embodiment,
even when the data flowing over the CPU BUS 110 is
stored, the data cannot be reproduced or used, as in
the first embodiment.

15 As a result, the wrongful conduct of making
unauthorized copies and selling the thus copied mediums
can be prevented, thereby protecting copyrights.

Furthermore, with the second embodiment, the
information that directly indicates the master key
20 used to encipher the first session key recorded on
the recording medium is not necessary, which enables
a suitable master key to be selected and used in
a predetermined range in recording the data on a DVD.
In addition, the second embodiment has the advantage
25 that it can allocate master keys in a specific unit,
such as a DVD maker or a DVD distributor.

With the second embodiment, because the circuits

used for enciphering and deciphering can be designed separately from the essential portion of the reproducing section of the digital recording and reproducing apparatus, such as a DVD, even if the cipher is broken, the deciphering unit 114a (or the enciphering unit 107 and deciphering unit 114a) has only to be replaced to overcome this problem.

While in the second embodiment, the enciphering unit 107 has one enciphering circuit, it may have two enciphering circuits. Moreover, although in the embodiment, deciphering unit 114a has one deciphering circuit, it may have two, three, four, or five deciphering circuits. In these cases, it is desirable that the enciphering circuits should be paired with the corresponding deciphering circuits and each pair be used independently.

When a set of an enciphering circuit and its corresponding deciphering circuit is used independently, an enciphering method different from that in another enciphering circuit and deciphering circuit may be used in the enciphering circuit and its corresponding deciphering circuit in the independent set.

Next, the operation of the second embodiment in the case of Method 2 where an n number of $E_{MKi}(S_K)$ ($i = 1$ to n) have been recorded on the DVD 101 and the deciphering unit 114a includes one M_{Kj} (j has a value in the range of 1 to n) will be explained by reference

to the flowcharts of FIGS. 7 and 8.

At step S11, the first session key $E_{SK}(S_K)$ enciphered using the first session key S_K itself is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the first session key, and then is loaded into the enciphering unit 107. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

At step S12, the first session key $E_{MKi}(S_K)$ ($i = 1$ to n) enciphered using the master key M_{Ki} is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the master key, and then is loaded into the enciphering unit 107. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

At step S13, the session key creation circuit 111 of deciphering unit 114a creates a second session key S_K' using random numbers, such as time data from a clock (not shown). Then, the deciphering circuit 112 decipheres the created second session key S_K' using the master key M_{Kj} (j has a predetermined value in the range of 1 to n) to create $D_{MKj}(S_K')$ and sends it to the enciphering unit 107 via the CPU BUS 110.

As the timing of generating random numbers (e.g., the timing of inputting time information), for example, the timing with which the signal indicating that the DVD 101 has been loaded into the DVD driving unit is

asserted may be used.

At step S14, using the master key M_{Kj} (j has a predetermined value in the range of 1 to n), the enciphering circuit 104 of the enciphering unit 107 enciphers $D_{MKj}(S_K')$ received via the CPU BUS 110.

Namely, from $E_{MKj}(D_{MKj}(S_K')) = S_K'$

a second session key S_K' created at the session key creation circuit 111 of the deciphering unit 114a can be obtained.

The second session key S_K' created at the session key creation circuit 111 is designed to prevent its contents from being known even if it is stolen on the CPU BUS 110.

Then, at step S15, using the thus obtained second session key S_K' , the enciphering unit 107 enciphers the enciphered first session key $E_{SK}(S_K)$ recorded on the DVD 101 to create $E_{SK'}(E_{SK}(S_K))$, and sends this to deciphering unit 114a.

Similarly, at step S16, using the thus obtained second session key S_K' , the enciphering unit 107 enciphers an n number of enciphered first session keys $E_{MKi}(S_K)$ recorded on the DVD 101 to create $E_{SK'}(E_{MKi}(S_K))$, and sends these to deciphering unit 114a via the CPU BUS 110.

Then, at step S17, the deciphering circuit 112 of the deciphering unit 114a deciphers $E_{SK'}(E_{SK}(S_K))$ received via the CPU BUS 110 using the second session

key S_K' and produces:

$$D_{SK'}(E_{SK'}(E_{SK}(S_K))) = E_{SK}(S_K)$$

Similarly, at step S18, the deciphering circuit 112 of the deciphering unit 114a deciphers

5 $E_{SK'}(E_{MKi}(S_K))$ received via the CPU BUS 110 using the second session key S_K' and produces:

$$D_{SK'}(E_{SK'}(E_{MKi}(S_K))) = E_{MKi}(S_K)$$

Because the master key M_{Ki} used in creating each of the n number of $E_{MKi}(S_K)$ ($i = 1$ to n) recorded on
10 the DVD 101 is unknown, it cannot be known whether the master key M_{Ki} corresponds to the master key M_{Kj} in the deciphering unit 114a. At step S19, the first session key S_K is found using the key judging circuit 120 as follows.

15 First, the principle of the key judging process will be explained.

When all of $E_{MKi}(S_K)$ ($i = 1$ to n) are deciphered using the master key M_{Kj} , this gives:

$$S_{Kij} = D_{MKj}(E_{MKi}(S_K)) \quad (i = 1 \text{ to } n)$$

20 Of these, one S_{Kij} (i is in the range of 1 to n) is the first session key S_K .

Using the $E_{SK}(S_K)$, it is determined which one of the created S_{Kij} ($i = 1$ to n) is the first session key S_K .

25 Then, when $E_{SK}(S_K)$ is deciphered using all of the candidates S_{Kij} ($i = 1$ to n) of the first session key, this gives:

$$S_{K''}(i, j) = D_{SKij}(E_{SK}(S_K))$$

Here, when the same master key M_{Kj} as the master key M_{Ki} used in creating $E_{MKi}(S_K)$ is used in the deciphering unit, or when $i = j$, this gives $S_{K''}(i, j)$
5 $= S_{Kij} = S_K$.

Therefore, when a check is made to see if $S_{K''}(i, j) = S_{Kij}$ ($j = 1$ to n) holds for each S_{Kij} ($i = 1$ to n), this gives S_{Kij} that meets $S_{K''}(i, j) = S_{Kij}$ ($j = 1$ to n) as the first session key S_K . The one corresponding
10 to i giving the S_{Kij} is the master key used in the present session.

For example, in FIGS. 6A and 6B, the deciphering circuit 112 in the key judging circuit 120 deciphers $E_{MKi}(S_K)$ for $i = 1$ using master key M_{Kj} , giving:

15 $S_{Kij} = D_{MKj}(E_{MKi}(S_K))$

Then, the deciphering circuit 112 deciphers $E_{SK}(S_K)$ using S_{Kij} , giving:

$$S_{K''} = D_{SKij}(E_{SK}(S_K))$$

Next, the comparison circuit 121 compares $S_{K''}$
20 with S_{Kij} . If they coincide with each other, the gate circuit 122 will be controlled so as to output the stored S_{Kij} (FIG. 6A) or $S_{K''}$ (FIG. 6B) as the first session key S_K .

If they do not coincide, i is incremented by one
25 and the same operation will be carried. This will be continued until the first session key S_K has been obtained.

After the first session key S_K has been obtained as described above, at steps S20 to S22, the image data Data is extracted from the image data $E_{SK}(\text{Data})$ enciphered using the first session key S_K .

5 As described earlier, the image data Data is decoded at the MPEG decoder circuit 115. After the decoded signal has been converted by the D/A converter circuit 116 into an analog signal, the analog signal is sent to the imaging device (not shown), such as
10 a television, which reproduces the image.

In Method 2, too, any one of step S11, step S12, and step S13 and step S14 may be executed first.

Moreover, either step S15 and step S17 or step S16 and S18 may be executed first.

15 Furthermore, steps S12, S16, S18, and S19 may be executed in a batch processing manner using all the n number of (enciphered) master keys recorded on the DVD or using a specific number of master keys at a time. They may be executed one after another for each master
20 key.

When they are executed sequentially every third master key, the second session key S_K' may be created for each master key.

25 Step S20 and step S21 may be executed by the method of carrying out the steps in units of $E_{SK}(\text{Data})$, the method of reading a specific number of $E_{SK}(\text{Data})$ at step S20, storing the read-out data in a buffer

temporarily, and then deciphering $E_{SK}(\text{Data})$ in the buffer at step S21, or the method of carrying out step S20 and step S21 in a pipeline processing manner.

Moreover, the deciphering unit 114a may transfer
5 the image data $E_{SK}(\text{Data})$ to the MPEG decoder circuit 115 in units of one Data item or a specific number of Data items.

As described above, with the second embodiment,
even when the data flowing over the CPU BUS 110 is
10 stored, the data cannot be reproduced or used, as in the first embodiment.

As a result, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

Furthermore, with the second embodiment, because
15 the first session keys enciphered using more than one master key and the first session key enciphered with the first session key itself are stored on the recording medium, the master keys built in the
20 deciphering unit can be allocated in a specific unit, such as to each unit manufacturer.

With the second embodiment, because the circuits
used for enciphering and deciphering can be designed
separately from the essential portion of the reproduc-
25 ing section of the digital recording and reproducing apparatus, such as a DVD, as seen from FIG. 1, even if the cipher is broken, the deciphering unit 114b (or the

enciphering unit 107 and deciphering unit 114b) has only to be replaced to overcome this problem.

While in the second embodiment, the enciphering unit 107 has one enciphering circuit, it may have two enciphering circuits. Moreover, although in the embodiment, the deciphering unit 114a has one deciphering circuit, it may have two, three, four, or five deciphering circuits. In these cases, it is desirable that the enciphering circuits should be paired with the corresponding deciphering circuits and each pair be used independently or be shared.

When a set of an enciphering circuit and its corresponding deciphering circuit is used independently, an enciphering method different from that in another enciphering circuit and deciphering circuit may be used in the enciphering circuit and its corresponding deciphering circuit in the independent set.

Next, explanation will be given about Method 3 where an n number of $E_{MKi}(S_K)$ ($i = 1$ to n) have been recorded on the DVD 101 and the deciphering unit 114a includes an m number of M_{Kj} (j takes m values in the range of 1 to n ($m < n$)).

Since Method 3 is the same as Method 2 in basic configuration, operation, and effect, only the difference between them will be explained.

While in Method 2, the deciphering unit 114a includes one predetermined master key M_{Kj} (j has

a value in the range of 1 to n), in Method 3, the
deciphering unit 114a includes an m number of
predetermined master keys M_{Kj} ($m \geq 2$). The order in
which the m number of master keys M_{Kj} (j takes m values
5 in the range of 1 to n) are used in the key judgment
has been determined.

Because an n number of $E_{MKi}(S_K)$ ($i = 1$ to n) have
been recorded on the DVD 101, using the master key
first in order of use in the deciphering unit 114b
10 produces the first session key S_K . Therefore, in this
case, the operation is the same as in Method 2.

With Method 3, if one of the master keys is broken,
the master key is made unusable. From this time on,
 $E_{MKi}(S_K)$ corresponding to the unusable master key is
15 not allowed to be recorded on the DVD 101. This case
will be explained below.

When the unusable master key is not the master key
first in order of use, the first session key S_K can be
obtained. In this case, too, the operation is the same
20 as in Method 2.

When the master key first in order of use is made
unusable, $E_{MKi}(S_K)$ corresponding to the unusable master
key has not been recorded on the DVD 101. Even if the
master key first in order of use is used, the first
25 session key S_K cannot be obtained in step S19. In such
a case, when the deciphering unit 114a carries out the
same operation using the master key second in order of

use as in Method 2, this produces the first session key S_K , provided that this master key is not unusable.

Even when the master key r -th in order of use is made unusable, the first session key S_K can be obtained
5 similarly, provided that one of the master keys $(r + 1)$ -th or later in order of use is not unusable.

In this way, the deciphering unit 114a can be used until the predetermined m number of master keys ($m \geq 2$) in the deciphering unit 114a have all been made
10 unusable.

The operation of Method 5 is the same as that of Method 3.

Because in Method 4, the information corresponding to all the master keys has not been stored on the DVD
15 101, when the information corresponding to the master key selected in the deciphering unit has not been recorded on the DVD 101, deciphering cannot be effected as in the case where the master key is unusable.
In this case, the master key next in order of use is
20 selected and deciphering is tried. Therefore, the operation of Method 4 is also the same as that of Method 3.

In the embodiment, to encipher the information and transfer it safely over the CPU BUS 110, the second
25 session key S_K' has been used. The second session key S_K' is created in the deciphering unit 114a and is transferred to the enciphering unit 107 through the

procedure of using master keys. At that time, one predetermined master key is supposed to have been registered in the enciphering unit 107.

5 Instead, a plurality of master keys may be registered in the enciphering unit 107 and the second session key S_K' may be transferred from the deciphering unit 114a to the enciphering unit 107, using the procedure as described in Method 1 to Method 5 using key judgment.

10 For example, when the same master key as that registered in the deciphering unit 114a is also registered in the enciphering unit 107, the operation is the same as that of Method 5.

15 When part of the master keys registered in the deciphering unit 114a are registered in the enciphering unit 107, the operation is the same as that of Method 3.

When one master key is registered in the enciphering unit 107, the procedure of Method 2 can be used.

20 In these cases, however, in the procedure of each of Method 1 to Method 5, enciphering is replaced with deciphering. Specifically, $D_{MKi}(S_K)$ and $D_{SK}(S_K)$ are transferred from the deciphering unit 114a to the enciphering unit 107.

25 In addition to the configuration using the master key, various suitable configurations may be used as the configuration that safely transfers the second session key S_K' from the deciphering unit 114a to the

enciphering unit 107 over the CPU BUS 110. For example, the techniques disclosed in Nikkei Electronics, No. 676, Nov. 18, 1996, pp. 13-14. In this case, it is not necessary to register a master key in the enciphering unit 107.

(Third Embodiment)

Hereinafter, a third embodiment of the present invention will be explained.

The third embodiment is, for example, a single DVD player.

FIG. 9 is a block diagram of a system according to the third embodiment of the present invention. An example of the operation of the third embodiment is shown in the flowchart of FIG. 10.

The third embodiment is what is obtained by eliminating from the configuration of the second embodiment the portion related to the operation of exchanging an enciphered key between the enciphering unit and deciphering unit by use of the second session key.

As shown in FIG. 9, the system of the third embodiment comprises a DVD driving unit (not shown) that reads the data from a DVD 101 and a deciphering unit 114b.

The deciphering unit 114b includes a deciphering circuit 112, a key judging circuit 120, a demodulation/error correction circuit 117, and a demodulation/error

correction circuit 118. In the third embodiment, the deciphering unit 114b is assumed to include an MPEG decoder circuit 115 and a conversion circuit 116 that converts the digital deciphered data into analog data.

5 As shown in FIGS. 6A and 6B, the key judging circuit 120 includes a deciphering circuit 112, a comparison circuit 121, and a gate circuit 122.

10 Although in FIG. 9 and FIGS. 6A and 6B, the deciphering unit 114b has a total of three deciphering circuits 112, including the two deciphering circuits 112 in the key judging circuit 120, it is assumed that it actually has one deciphering circuit. Each of the demodulation/error correction circuit 117 and the demodulation/error correction circuit 118 may be
15 provided in the unit in the preceding stage, not in the enciphering unit 107.

 The deciphering unit 114b is composed of a single independent IC chip.

20 In the deciphering unit 114b, a master key, explained later, has been registered. It is assumed that the master key has been recorded in a secret area in the deciphering unit chip so that the user cannot externally take out the master key.

25 In the third embodiment, there are an n number of master keys. A first session key is represented by S_K , a second session key S_K' , the i-th master key M_{Ki} (i is in the range of 1 to n), and image data (i.e., the data

to be enciphered) Data.

In FIG. 9, numeral 102-1 indicates $E_{MKi}(S_K)$ created by enciphering the first session key S_K using the master key M_{Ki} , 102-2 $E_{S_K}(S_K)$ created by enciphering the first session key S_K using the first session key S_K itself, 103 $E_{S_K}(\text{Data})$ created by enciphering the image data Data using the first session key S_K , 105 the master key M_{Ki} , and 113 the first session key S_K .

As in the second embodiment, several methods can be considered as to how to set the number of types of $E_{MKi}(S_K)$ created by enciphering the first session key S_K recorded on the DVD 101 using the master key M_{Ki} and how to set the number of types of master key M_{Kj} the deciphering unit 114b has in it. For example, they are as follows.

(Method 1) One master key $E_{MKi}(S_K)$ (i is in the range of 1 to n) is recorded on the DVD 101. The deciphering unit 114b has an n number of master keys M_{Kj} ($j = 1$ to n) in it.

(Method 2) An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114b has one master key M_{Kj} (j has a value in the range of 1 to n) in it.

(Method 3) An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114b has an m ($2 < m < n$) number of

master keys M_{Kj} (j is in the range of 1 to n) in it.

(Method 4) An m ($2 < m < n$) number of master keys $E_{MKi}(S_K)$ (i is in the range of 1 to n) are recorded on the DVD 101. The deciphering unit 114b has an n number of master keys M_{Kj} ($j = 1$ to n) in it.

(Method 5) An n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are recorded on the DVD 101. The deciphering unit 114b has an n number of master key M_{Kj} ($j = 1$ to n) in it.

As shown in FIG. 3, it is assumed that on the DVD 101, one (in the case of Method 1) or more (in the case of Method 2 to Method 5) $E_{MKi}(S_K)$ created by enciphering the first session key S_K using the master key M_{Ki} are recorded in the key recording area (lead-in area) in the innermost circumference portion and the $E_{SK}(\text{Data})$ created by enciphering the image data Data using the first session key S_K is recorded in the data recording area (data area).

Next, the operation of the third embodiment will be explained by reference to the flowchart of FIG. 10. The operation of the third embodiment is what is obtained by eliminating from the operation of the second embodiment the portion related to the operation of exchanging an enciphered key between the enciphering unit and deciphering unit by use of the second session key.

At step S31, the first session key $E_{SK}(S_K)$

enciphered using the first session key S_K itself is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the first session key, and then is loaded into the deciphering unit 114b. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

At step S32, the first session key $E_{MKi}(S_K)$ enciphered using the master key M_{Ki} is read from the DVD 101, on which the DVD driving unit (not shown) has recorded the master key, and then is loaded into the deciphering unit 114b. At that time, the demodulation/error correction circuit 117 performs demodulation and data error correction.

At step S33, the first session key S_K is obtained using the key judging circuit 120.

The operation of obtaining the first session key S_K differs depending on Method 1, Method 2, or Method 3 to Method 5. Each case is the same as explained in the second embodiment, so explanation of them will not be given.

After the first session key S_K has been obtained, the image data Data is extracted from the enciphered image data $E_{S_K}(\text{Data})$ using the first session key S_K at steps S34 to S36. The operation at step S34 to S36 are the same as that of steps S20 to S22 explained in the second embodiment (i.e., that of steps S6 to S8 explained in the first embodiment) except that there is

no exchange of the image data Data between the units via the CPU BUS.

As described earlier, the image data Data is decoded at the MPEG decoder circuit 115. After the
5 decoded signal has been converted by the D/A converter circuit 116 into an analog signal, the analog signal is sent to the imaging device (not shown), such as a television, which reproduces the image.

In Method 3, too, step S31 may be executed before
10 step S32 or vice versa.

Furthermore, in method 2 and in method 3 to method 5, step S32 and step S33 may be executed in a batch processing manner using all the n number of (enciphered) master keys (in the case of Methods 2, 3,
15 and 5) or all the m number of (enciphered) master keys (in the case of Method 4) recorded on the DVD or using a specific number of master keys at a time. They may be executed one after another for each master key.

Step S34 and step S35 may be executed by the
20 method of carrying out the steps in units of $E_{SK}(\text{Data})$, the method of reading a specific number of $E_{SK}(\text{Data})$ at step S34, storing the read-out data in a buffer temporarily, and then deciphering $E_{SK}(\text{Data})$ in the buffer at step S35, or the method of carrying out step
25 S34 and step S35 in a pipeline processing manner.

Moreover, the deciphering unit 114b may transfer the image data $E_{SK}(\text{Data})$ to the MPEG decoder circuit

115 in units of one Data item or a specific number of Data items.

With the third embodiment, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

Furthermore, with the third embodiment, it is possible to select and use a suitable master key in a predetermined range in recording the data on a DVD. The master keys can be allocated in a specific unit, such as to a DVD player maker, a DVD maker, or a DVD distributor.

Still furthermore, with the third embodiment, because the circuits used for enciphering and deciphering can be designed separately from the essential portion of the reproducing section of the digital recording and reproducing apparatus, such as a DVD, as seen from FIG. 1, even if the cipher is broken, the deciphering unit 114b has only to be replaced to overcome this problem.

While in the third embodiment, the deciphering unit 114b has one deciphering circuit, it may have two or three deciphering circuits. In these cases, it is desirable that the enciphering circuits should be paired with the corresponding deciphering circuits and each pair be used independently or be shared.

When a set of an enciphering circuit and its corresponding deciphering circuit is used independently,

an enciphering method different from that in another enciphering circuit and deciphering circuit may be used in the enciphering circuit and its corresponding deciphering circuit in the independent set.

5 Until now, the first embodiment, the second embodiment (specifically, the three types of configuration), and the third embodiment (specifically, the three types of configuration) have been explained. The present invention is not limited to these embodiments,
10 but may be practiced or embodied in still other ways without departing from the spirit or essential character thereof.

 Although the embodiments have been explained using a DVD as information recording medium, the present
15 invention may be applied to other recording mediums, such as CD-ROMs.

 While in the embodiments, the image data has been used as the information to be deciphered, the present
20 invention may be applied to reproducing devices of other types of information, such as sound, text, or programs.

 While in the embodiments, the data Data is image data, the configuration may be designed to use key information S_{Kt} as the data Data. Specifically,
25 $E_{SK}(S_{Kt})$ and $E_{SKt}(\text{Data})$ may be recorded on a recording medium, such as a DVD, beforehand in place of $E_{SK}(\text{Data})$, then S_{Kt} is first obtained at the deciphering units 114,

114a, 114b through the procedure in each of the
embodiments, and $E_{SKt}(\text{Data})$ is deciphered using the
 SKt to produce the actual contents of the data.
The hierarchization of keys may be carried out over any
5 number of levels of hierarchy.

While in the embodiments, the information to be
deciphered has been compressed according to the MPEG2
standard, the present invention is not restricted to
this. The data may be compressed or enciphered
10 according to another standard. In this case, a decoder
circuit corresponding to another standard has to be
provided instead of the MPEG decoder circuit 115.
The data may not be enciphered. In this case, the MPEG
decoder circuit 115 is eliminated.

15 To output any data items compressed by various
methods (or data items requiring no deciphering),
several types of decoder circuits may be provided and
switched suitably. In this case, a method can be
considered which reads an identifier indicating the
20 decoder to be used from a recording medium, such as a
DVD, and selects a suitable decoder circuit according
to the identifier.

The configurations of the key judging circuit 120
shown in FIGS. 6A and 6B in the second and third
25 embodiments are illustrative and not restrictive.
Other configurations of the key judging circuit may be
considered.

Various types of the configuration that uses $E_{SK}(S_K)$ as key judgment information may be considered. For instance, $D_{SK}(S_K)$ is used as information used for key judgment. The key judging circuit 120 deciphers $E_{MKi}(S_K)$ read from a recording medium, such as a DVD, using master key M_{Kj} to produce $S_{Kij} = D_{MKj}(E_{MKi}(S_K))$, deciphers the S_{Kij} using the S_{Kij} itself to produce $S_{K'''} = D_{SKij}(S_{Kij})$, and compares the $S_{K''}$ with $D_{SK}(S_K)$ read from a recording medium, such as a DVD. When they coincide with each other, the key judging circuit judges that the first session key $S_K = S_{Kij}$ is correct and outputs it.

As other examples of key judgment information, the one enciphered or deciphered twice or more times, such as $E_{SK}(E_{SK}(S_K))$ or $D_{SK}(D_{SK}(S_K))$ may be considered. In addition, $E_{MKi}(E_{MKi}(S_K))$ may be provided for each $E_{MKi}(S_K)$.

In the embodiments, on the basis of the key judgment information, a judgment is made through the procedure shown in each of Method 1 to Method 5 as to whether the key obtained by deciphering is the correct first session key. However, the key judgment information, key judging procedure, and the structure for key judgment can be eliminated by recording all the $E_{MKi}(S_K)$ on a recording medium, such as a DVD, in order of i and registering them in the deciphering unit in such a manner that i corresponds to M_{Ki} . When M_{Ki} for

a certain i becomes unusable, it is desirable that information indicating invalidity should be stored on a recording medium, such as a DVD, in place of $E_{MKi}(S_K)$.

A key control method followed by disk makers
5 (assumed to be makers that produce DVDs for writings, including movies and music), player makers (assumed to be makers that produce DVD players), and a key control organization that controls master keys will be described taking a DVD-ROM as example, by reference to
10 FIG. 11. Here, in addition to the contents, Data may be key information, as described earlier (explanation of the case where enciphering or deciphering is done using key information S_{Kt} when Data is key information S_{Kt} will be omitted). In FIG. 11, a computer used for
15 processing is not shown.

FIG. 12 is a diagram to help explain a system for deciphering. Enciphering circuits 301, 312, 303 in FIG. 12 may be on the same unit (e.g., a computer) or on different units (e.g., computers). In the latter
20 case, information is exchanged between the units. The enciphering circuits 301, 312, 303 may be constructed in hardware or in software.

Explanation will be given about a case where an n number of master keys $E_{MKi}(S_K)$ ($i = 1$ to n) are
25 recorded on a DVD. A DVD player (a deciphering unit 114b) has an m ($2 < m < n$) number of master keys M_{Kj} (j is in the range of 1 to n) in it. The m number of

master keys have been selected from the n number of master keys beforehand. The master keys M_{Kj} are assumed to be allocated exclusively to the DVD player maker. It is assumed that $n = 100$ and $m = 10$.

5 A method of recording $E_{SK}(S_K)$ on a DVD as key judgment information is used (the section indicated by numeral 302 in FIG. 12 uses $E_{SK}(S_K)$ as key judgment information).

10 A key control organization 200 keeps master keys M_{Ki} ($i = 1$ to 100). It is desirable that the number of master keys should be set at a larger value than necessary in preparation for the entry of a new player maker or in case a master key is broken.

15 The key control organization 200 exclusively allocates the master keys M_{Ki} ($i = 1$ to 100) to the individual player makers 201 to 203. For example, as shown in FIG. 11, it allocates master keys M_{Ki} ($i = 10$ to 19) to player maker A, master keys M_{Ki} ($i = 20$ to 29) to player maker B, and master keys M_{Ki} ($i = 30$ to 39) to player maker C. The key control organization 200 sends the allocated master keys to the individual player makers by means of communication mediums or recording mediums. At that time, it is desirable that they should be exchanged safely by enciphered
20
25 communication.

Each player maker controls the master keys allocated by the key control organization 200.

Using the allocated master keys, each player maker manufactures DVD players with the configuration as shown in the third embodiment and sells the resulting products.

5 It is assumed that the key control organization 200 does not give the plain data on the master keys to disk makers 221 to 223.

First, each disk maker (e.g., maker a) determines the first session key S_K (e.g., for each disk) by
10 itself, and gives the first session key S_K to the key control organization 200. The key control organization 200 enciphers the received first session key S_K using all the master keys M_{Ki} ($i = 1$ to 100) to produce $E_{MKi}(S_K)$ ($i = 1$ to 100) (using the enciphering unit 301
15 of FIG. 12). Then, the key control organization 200 gives $E_{MKi}(S_K)$ ($i = 1$ to 100) to disk maker a.

It is desirable that the exchange of the allocated master keys between the key control organization 200 and the disk maker should be made by means of
20 communication mediums or recording mediums through enciphered communication.

Disk maker a records $E_{MKi}(S_K)$ ($i = 1$ to 100), $E_{SK}(S_K)$, and $E_{SK}(\text{Data})$ on a DVD 231. The operation of enciphering S_K with S_K itself to produce $E_{SK}(S_K)$ is
25 carried out by the disk maker side or by the key control organization 200 side (using the enciphering circuit 321 of FIG. 12) in the case of enciphering

with a mater key. It is assumed that at least the enciphering of the contents is done at the disk maker side (using the enciphering circuit 303 of FIG. 12).

5 Disk maker a controls the received $E_{MKi}(S_K)$, key judgment information $E_{SK}(S_K)$, and $E_{SK}(\text{Data})$ (or Data) for S_K , for example.

The same is true for the other disk makers.

10 In case it is found that the master key has been broken, from that time on, DVDs are manufactured without using the broken master key. For example, if the master key for $i = 19$ has been broken, ninety-nine $E_{MKi}(S_K)$ corresponding to $i = 1$ to 18 and 20 to 100 are recorded on a DVD.

15 In case it is found that the master key has been broken, it is desirable that the player maker to which the broken master key has been allocated should manufacture and sell DVD players excluding the broken master key. For example, if the master key for $i = 19$ has been broken, player maker A manufactures DVD
20 players using the master keys for $i = 10$ to 18 and sells the resulting products.

The already sold DVD player having the master key for $i = 19$ may be used without any modification. It may be modified so as not to have the master key for
25 $i = 19$.

Consequently, the master keys can be controlled safely and effectively. In addition, the risk of the

master key being deciphered in an unauthorized manner can be dispersed and even after the deciphering of the master key, the system can function safely and effectively.

5 As describe in detail, with the present invention, only the correct maker having at least one of a plurality of second keys can get the first key and therefore can get the plain data of the data enciphered using the first key.

10 As a result, the wrongful conduct of making unauthorized copies and selling the thus copied mediums can be prevented, thereby protecting copyrights.

Additional advantages and modifications will readily occur to those skilled in the art. Therefore,
15 the present invention in its broader aspects is not limited to the specific details, representative devices, and illustrated examples shown and described herein. Accordingly, various modifications may be made without departing from the spirit or scope of the general
20 inventive concept as defined by the appended claims and their equivalents.
